# LOW JITTER INPUT BUFFER WITH SMALL INPUT SIGNAL SWING

#### **Background of the Invention**

Field of the Invention

[0001] The present invention generally relates to an interface circuit, and particularly to a low jitter input buffer.

**Description of Related Art** 

10

15

[0002] Major design efforts have been directed at circuit design techniques involving input circuits for memory devices. A number of solutions have been proposed.

[0003] U.S. Patent 5,978,310 (Bae et al) describes an input buffer for a DRAM memory device, which removes noise from the row address strobe. The device has a data output enable, which can be delayed for a predetermined time, and which also produces a contr o! signal for the output. There is also a buffer output for producing the noise free input according to the control signal.

December 20, 2004

[0004] U.S. Patent 6,002,618 (Komarek et al) discloses an NMOS input

receiver circuit for a read only memory. It includes a feedback loop to

control hysteresis. There is a second stage and an additional output for

the receiver. Switching noise from inside the memory is isolated and

cannot be fed back into the receiver circuit to affect the TTL voltage levels.

Wide, long FET sizes are used to minimize manufacture variations in the

receiver switching levels.

[0005] What is still needed is a mechanism by which an input buffer works

in the presence of ground noise, specifically how capacitance can be used

to reduce such noise for a memory input circuit.

### Summary of the Invention

[0006] It is therefore an object of the present invention to provide an efficient circuit design technique for an input buffer receiver for a particular memory device[[,]] that works to filter ground noise. It is a further object of the invention to provide a means for reducing jitter in an input buffer. This is achieved by attaching a large capacitance to the PMOS bias node of

the input buffer receiver.

[0007] These and other objects are achieved by an input buffer receiver

comprising: a buffer input portion for receiving an input signal SIGNAL\_IN;

5

10

15

Attorney Docket: ET01-010 Reply to Notice of Noncompliance of Amdt. Dated: January 5, 2005

December 20, 2004

a large capacitor capacitance CHC between a PMOS bias node and a VSS source lower supply voltage VSS, and a buffer output portion for producing an output signal SIGNAL\_OUT1. Furthermore, in the input buffer receiver, the VB11 gate biasing voltage of the bias node of transistors P11 and P12 is charge coupled to the VSS-lower voltage source voltage. This results in a quicker response time for the output signal SIGNAL OUT1.

#### **Brief Description of the Drawings**

- The foregoing and other objects, aspects, and advantages will be [8000] better understood from the following detailed description of a preferred embodiment of the invention, with reference to the drawings, in which:
- FIG. 1 is a diagram of an input buffer receiver according to the prior [0009] art.
- FIG. 2 is a diagram of an input buffer receiver according to the [0010] present invention.
- FIGS.3A-B show the timing diagrams of the input buffer receiver of [0011] the present invention and the definitions of JITTER\_RISE and JITTER FALL.

Amdt. Dated: January 5, 2005

Reply to Notice of Noncompliance of December 20, 2004

December 20, 2007

[0012] FIGS. 4A-B illustrate the workings of capacitance capacitor CHC to reduce JITTER\_RISE and JITTER\_FALL.

#### **Detailed Description of the Invention**

[0013] One embodiment of the present invention is provided below with reference to the accompanying diagrams.

5

10

15

[0014] Referring to FIG. 1, the input buffer receiver of the prior art includes a buffer input portion 100 for receiving an input signal SIGNAL\_IN and a buffer output portion 200 for producing an output signal SIGNAL\_OUT.

and N2, where a lower supply voltage VSS is applied to the source nodes of NMOS transistors N1 and N2, and PMOS transistors P1 and P2, where an upper voltage supply VDD is applied to the source nodes. The gate nodes of transistors P1 and P2 and the the drains of transistors N1 and P1 are connected together to form the biasing node b1. The biasing voltage VB1 is developed at the biasing node b1 as a result of the configuration of transistors P1 and P2. A parasitic capacitor Cp is present from the biasing node b1 to the ground reference node. and a signal VB1 is applied to the gate nodes of P1 and P2. In the prior art, a reference voltage VREF is applied to the gate of transistor N1, input signal SIGNAL\_IN is applied to

Attorney Docket: ET01-010
Reply to Notice of Noncompliance of

December 20, 2004

the gate of <u>transistor\_N2</u>, and VB1 is applied to the drain of N1 and the drain of P1, as well as the PMOS bias node of P1 and P2. <u>Input signal</u> SIGNAL\_IN is a low swing signal coming from off chip. The buffer output portion 200 is comprised of a common node for the drain of <u>transistor\_N2</u> and drain of <u>transistor\_P2</u>, which serves as input to inverter I1. The output of inverter I1 is the output signal <u>output SIGNAL\_OUT</u>.

The ground noise (VSS noise), as described above, is developed between the lower supply voltage VSS and the ground reference voltage.

The magnitude of the VSS noise affects the delay timing from the input signal SIGNAL IN to the output signal SIGNAL OUT. The variation in the delay causes jitter in the rise and fall delays of the buffer and thus slower response times.

[0017] Referring to FIG. 2, the proposed invention is comprised of a similar buffer input portion 101 and a similar buffer output portion 201. The buffer input portion 101 is comprised of: NMOS transistors N11 and N12, where a-the lower supply voltage VSS is applied to the source nodes of N11 and N12, and PMOS transistors P11 and P12, where an upper supply voltage VDD is applied to the source nodes. The gate nodes of transistors P11 and P12 and the the drains of transistors N11 and P11 are connected together to form the biasing node b11. The biasing voltage VB11 is

15

5

10

Attorney Docket: ET01-010 Appl. No.: 10/631,84

5

10

15

Reply to Notice of Noncompliance of Amdt. Dated: January 5, 2005

December 20, 2004

developed at the biasing node b11 as a result of the configuration of transistors P11 and P12. A parasitic capacitor Cp is present from the biasing node b11 to the ground reference node. A signal VB11 is applied to the gate nodes of P11 and P12. A reference supply voltage VREF is applied to the gate of transistor N11, input signal SIGNAL\_IN is applied to the gate of N12, and VB11 is applied to the drain of N11 and the drain of P11. In the present invention, a large capacitance capacitor CHC is attached between the PMOS bias node VB11 b11 and the lower supply source voltage VSS. The buffer output portion 201 is comprised of a common node for the drain of transistor N12 and the drain of transistor P12, which serves as input to inverter I11. The output of inverter I11 is the output signal SIGNAL OUT1 of the invention.

The large capacitance CHC is in series with the parasitic capacitor [0018] Cp capacitance of the input buffer receiver devices transistors N11, P11, and P12. The large capacitor CHC, as connected, is designed to have an extremely large capacitance relative to the parasitic capacitor Cp such that the bias voltage VB11 essentially follows the voltage changes in the lower supply voltage VSS preventing the effects of the VSS noise. This coupling ratio is determined by the formula:

Amdt. Dated: January 5, 2005

Attorney Docket: ET01-010

Reply to Notice of Noncompliance of

December 20, 2004

$$\frac{\text{CHC}}{\text{Cp+CHC}} \approx 1$$

where:

CHC is the capacitance value of the large capacitor

CHC.

Cp is the capacitance value of the parasitic capacitor

Cp.

[0019] Because of its large coupling ratio (very close to 1), the capacitor

CHC essentially charge couples the biasing voltage VB11 gate voltage of

the PMOS bias node b11, to the VSS source lower supply voltage VSS, of

devices N11 and N12. This forces the transistors N11 and N12 to activate

and deactivate essentially simultaneously, allowing for a quicker response

time on output signal SIGNAL\_OUT1.

[0020] FIGS. 3A-B are diagrams of timed operation showing the input signal SIGNAL\_IN, the source-lower supply voltage VSS, and the output signal SIGNAL\_OUT1 of the proposed invention. It should be noted that the input signal SIGNAL\_IN is defined as VIH=VREF+350mv and VIL=VREF-350mv, and VSS is 200mv. The output signal SIGNAL\_OUT1 is defined by the delayed signal delay times\_DELTA1 or DELTA2, when

Page 34 of 88

10

15

5

Attorney Docket: ET01-010 Reply to Notice of Noncompliance of

December 20, 2004

input signal SIGNAL\_IN rises, and the delay times DELTA3 or DELTA4, when the input signal SIGNAL IN falls. The delay time DELTA1 is defined as the delay from the rising edge of input signal SIGNAL\_IN to the rising edge of output signal SIGNAL\_OUT, when VSS=200mv. It is the delay on output signal SIGNAL OUT1 when transistor N12 sees VSS noise and turns on weakly. The delay time DELTA2 is defined as the delay from the rising edge of input signal SIGNAL\_IN to the rising edge of output signal SIGNAL OUT1, when VSS=0v. It is the delay on of the output signal SIGNAL OUT1 when transistor N12 does not see VSS noise and turns on strongly. The delay time DELTA3 is defined as the delay from the falling edge of input signal SIGNAL IN to the falling edge of output SIGNAL\_OUT1, when VSS=0v. It is the delay on of the input signal SIGNAL OUT1 when transistor N12 does not see VSS noise and turns off weakly. DELTA4 is defined as the delay from the falling edge of input signal SIGNAL IN to the falling edge of output signal SIGNAL OUT1, when VSS=200mv. It is the delay seen on output signal SIGNAL OUT1 when transistor N12 sees VSS noise and turns off strongly. By definition, the delay times DELTA2 and DELTA4 are smaller than the delay times DELTA1 and DELTA3. The rise time jitter JITTER\_RISE is the difference between the delay times DELTA1 and DELTA2 when the input signal SIGNAL IN rises and the fall time jitter JITTER FALL is the difference

December 20, 2004

between the delay times DELTA3 and DELTA4 when input signal SIGNAL\_IN falls. The intent of the invention capacitance large capacitor CHC is to reduce rise time jitter\_JITTER\_RISE and fall time jitter JITTER\_FALL by primarily having devices transistors P12 and N12, activate, in the presence or absence of ground noise, almost simultaneously.

[0021] FIGS. 4A-B illustrate the workings of <u>large capacitor CHC. In Fig.</u>

4a, the large capacitor is shown in series with the parasitic capacitor Cp.

The Its large capacitance coupling ratio of the large capacitor CHC versus the capacitance of the parasitic capacitor Cp creates a charge coupling couples of the PMOS bias node, VB11 b11, of the input buffer receiver, to the VSS source lower supply voltage VSS, of the input buffer receiver.

This results in a quicker response time for a input signal SIGNAL OUT1.

[0022] While the invention has been described in terms of the preferred embodiments, those skilled in the art will recognize that various changes in form and details may be made without departing from the spirit and scope of the invention. The present invention covers modifications that fall within the range of the appended claims and their equivalents.

[0023] While this invention has been particularly shown and described with reference to the preferred embodiments thereof, it will be understood by Page 36 of 88

#### **Abstract**

[0025] A particular input buffer receiver includes a buffer input portion for receiving an input signal-SIGNAL\_IN, a large <u>capacitor eapacitance CHC</u> between the PMOS <u>a</u> bias node and the <u>VSS source lower supply</u> voltage, and a buffer output portion for producing an output signal-SIGNAL\_OUT1.

The circuit works to remove ground noise by charge coupling the <del>VB11</del> bias voltage <u>developed at the bias node</u> to the <del>VSS source lower supply</del> voltage of the input device.
